Constant Current LED Driver with PWM Dimming Control

**GENERAL DESCRIPTION**
The NJW4615A is a constant current LED driver with PWM dimming control. The output current can be set by external sensing resistor, and the NJW4615A can set up to 100mA. Because the withstand voltage of the output (LED) pin is 35V, it can series-connect the LED depending on forward voltage of the LED. The LED dimming control can be regulated via PWM duty cycle. It is suitable for back light, light source and so on.

**FEATURES**
- Supply Voltage Range 2.5V to 35V
- Output Voltage \( V_{LED} = 35V \) max.
- Output Current \( I_{LED} = 5mA \) to \( 100mA \)
- Output Current Accuracy \( \pm 1.2\% \)
- To 10 of White LED can be operated. (at LED \( V_f = 3.2V \))
- Quiescent Current 370\( \mu A \) max.
- PWM Dimming Control
- Enable Function
- Over Current Protection (with Hysteresis)
- Thermal Shutdown Protection
- LED Short Protection
- Package SOT-23-6-1

The number of LED series connection

It is necessary to drive LED that is the LED forward voltage ($V_f$) or more. When the LED was series connected, the supply voltage should be input sum of LED $V_f$ ($\Sigma V_f$) the series connected or more. In NJW4615A, it is necessary as minimum $V^+$ that is $\Sigma V_f + \text{NJW4615A output voltage}$ ($V_{\text{LED}} = 1V$). The maximum LED connected number that NJW4615A can drive is limited by the recommended output voltage maximum value (35V). Moreover, it should be used with $\Sigma V_f$ within 34V that is subtracted the $V_{\text{LED}} = 1V$.

The table below shows maximum LED number at each $V_f$. (All LED $V_f$ assumes ideally same)

<table>

PWM input pulse and PWM dimming accuracy

The \( I_{LED} \) transient behavior corresponding to PWM input pulse has some delay at rise/fall time.

![PWM Input Pulse and Output Current Pulse](image)

If enter a PWM signal with short pulse width, for the output current pulse width error becomes larger against the PWM input pulse width, it is incapable of accurate PWM dimming. The Output current pulse width error rate (\( \varepsilon \)) becomes the following value. (\( \varepsilon = t_{PWM\text{-ON}} - t_{PWM\text{-OFF}} \))

\[
\varepsilon_i = \text{approx.} \, 2\mu\text{s} \quad \text{(Output Current: } I_{LED}=20\text{mA, } T_a=25^\circ\text{C typ. <Reference Value> )}
\]

The actual value of the output current pulse width error rate can calculate by above error rate (\( \varepsilon_i \)) and the frequency and Duty of the PWM input pulse. (\( f_{PWM}\): PWM input pulse frequency, D: PWM input pulse Duty)

Based on the allowable value of the output current pulse width error rate, you should determine the frequency and Duty of the PWM input pulse.

\[
PWM \text{ Input pulse width } = \frac{D}{100} \times \left( \frac{1}{f_{PWM}} \right)
\]

\[
\text{Output Current pulse width } = \text{PWM Input pulse width} - \varepsilon_i
\]

\[
\text{Output Current pulse width error rate } = \frac{\text{(Output Current pulse width} - \text{PWM Input pulse width})}{\text{PWM Input pulse width} \times 100}
\]

\[
\text{Output Current pulse width error rate } = \frac{\varepsilon_i}{\text{PWM Input pulse width}} \times 100 \%\]

【Output current pulse width error rate calculation example: operation with PWM input pulse frequency 200Hz and Duty1%】

\[
PWM \text{ Input pulse width } = 1 \% \times \frac{1}{200} = 0.5 \% \times 100 \times 200 = 50 \mu\text{s}
\]

\[
\text{Output Current pulse width error rate } = \frac{-2 \mu\text{s}}{50 \mu\text{s}} \times 100 = -4 \%
\]

【Measurement Conditions】

- Output Current (\( I_{LED} \))
  - 5mA \( (R_o = 40\Omega) \)
  - 20mA \( (R_o = 100\Omega) \)
  - 100mA \( (R_o = 2\Omega) \)
- Supply Voltage
  - 12V
- Output (LED) pin
  - Input Voltage at 1V
- PWM Input Pulse
  - 200Hz, 0 to 5V
- Output Current \( I_{LED} \) Pulse Width
  - The time is more than 90% of set current.
- Ambient Temperature
  - \( T_a=25^\circ\text{C} \)
Protection Circuit

- Over Current Protection (Refer to Maximum Output Current vs. Output Pin Voltage)
  This protection function limits the output current, when the RS pin and GND pin was shorted. The limited current is dependence on output (LED) pin voltage.
  When the output (LED) pin voltage is less than "LED Short Protection Detect Voltage", maximum output current is limited to approx. 170mA (output (LED) pin voltage=1V, Ta=25°C).
  The output current returns to set current, when the short status is release.

- LED Short Protection (Refer to Maximum Output Current vs. Output Pin Voltage)
  This protection function limits the output current, when the output (LED) pin rises as in LED shorten at output FET ON.
  The output current is limited to approx. 60mA when the output (LED) pin voltage rose to approx. 20V.

- Thermal Shutdown Function (Refer to Output Current vs. Temperature)
  When junction temperature of the NJW4615A exceeds the 170°C*, internal thermal shutdown circuit function stops the device function. When junction temperature decreases to 150°C* or less, the device operation returns to normal operation.
  The purpose of this function is to prevent malfunctioning of IC at the high junction temperature. Therefore it is not something that urges positive use. It should make sure to operate within the junction temperature range rated (≤+150°C).
  *) Design value
The Loss of Constant Current Driver

The power consumption of the LED lighting circuit is classified as "the power consumption of the constant current driver" "the power consumption of the LED" and "the power consumption of the current sense resistor (R_S)". The loss of constant current driver is caused mainly by quiescent current (I_DD) and output current (I_LED).

The power dissipation of the device can calculate by follow equation.

\[
P_D \approx V_{DD} \times I_{DD} + (V_{LED} - V_{RS}) \times I_{LED} \\
= V_{DD} \times I_{DD} + (V' - \Sigma LED Vf - 0.2) \times I_{LED} \text{[W]}
\]

Rs pin voltage (V_{RS}): 0.2V

\[\Sigma \text{LED Vf represents the sum of the LED Vf of use.}\]

e.g.)
\[V_{DD} = V' = 12[V], I_{DD} = 260[\mu A], \Sigma LED Vf = 9[V], I_{LED} = 100[mA] \]

\[P_D \approx 12[V] \times 260[\mu A] + (12[V] - 9[V] - 0.2[V]) \times 100[mA] \approx 283[mW]\]

As shown in the above equation, the loss of constant current driver will increase in proportion to the voltage difference between the LED driving voltage V' and \(\Sigma \text{LED Vf}\).

It should set the LED operating Voltage (V') and output current (I_{LED}) with consideration of P_D.

The device power dissipation must be below the power dissipation rate of the device package including thermal derating to ensure correct operation.

Parallel Drive of NJW4615A

For applications that require more than 100mA, it can correspond by parallel connecting two or more NJW4615A. The LED current becomes sum of LED current of each NJW4615A.

Each device accepts different set current.

\[ I_{\text{LED}} = I_{\text{LED1}} + I_{\text{LED2}} = 0.2 / R_{S1} \, \Omega + 0.2 / R_{S2} \, \Omega \]

(e.g. \( I_{\text{LED}} = 150 \, \text{mA} \) setting: \( R_{S1} = 4 \, \Omega \), \( R_{S2} = 2 \, \Omega \))
